# Set 11: Ordered Dictionary Abstract Data Types: AVL Trees

CS240: Data Structures and Data Management

Jérémy Barbay

### Outline

### **AVL** Trees

Definition Height of AVL Trees Balancing operations

# Binary Search Trees

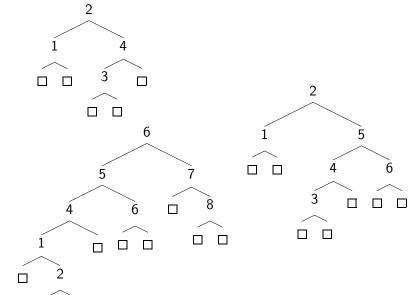

- ► The worst-case performance is
- Randomly built trees perform well
  - Expected height  $h = 1.386 \log(n+1)$
- ▶ Sequence of  $n^2$  alternating inserts/deletes
  - Expected height  $h \in \Theta(\sqrt{n})$
- Possible improvements?

# Height Balanced Trees

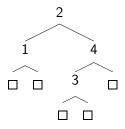

- ► Can we guarantee tree height?
  - ▶ Try to keep our search trees balanced
  - ▶ Must not affect the running time
- Balanced Node
  The heights of its subtrees differ by at most one
- AVL Tree
  A Binary Search Tree such that every node is balanced
  - Adel'son-Vel'skii and Landis, 1962

# Which Trees are AVL?

Which nodes are balanced?

# Recording Balance

- We can explicitly record a height for each node It would take bits per node.
- Or we can use condition codes
  - ► = Balanced
  - > Left-heavy (by one)
  - < Right-heavy (by one)</p>

It would take bits per node.

# AVL Tree Height

General Idea

Let S(h) be the fewest possible nodes for an AVL tree of height h (including placeholders)

S(1)

*S*(2)

*S*(3)

$$S(h) =$$

# AVL Tree Height

General Idea

#### **Theorem**

h is  $\Theta(\log n)$  for an AVL tree of height h and n internal nodes.

### Proof:

▶ Recurrence relation (close to Fibonaci Sequence) gives

$$S(h) = \frac{\left(\frac{1+\sqrt{5}}{2}\right)^{h+2}}{\sqrt{5}} + 1$$

▶ Note:  $S(h) \le n$ .

$$h \leq \frac{\lg n}{\lg \frac{1+\sqrt{5}}{2}} + o(1)$$
$$\approx 1.44 \lg n$$

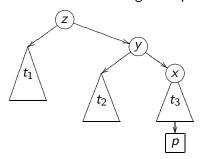

### **Operations**

- ▶ Find:
  - As in a Binary Search Tree (BST).
- ▶ Insert
  - Find and insert as in a BST.
  - Update heights (codes) on path back to root
  - Locate a possible unbalanced node, z
  - Perform a rotation (see two next slides)
- ▶ Delete
  - Find and delete as in a BST
  - Update heights (codes) on path back to root
  - ► Locate possible unbalanced nodes and rotate them.

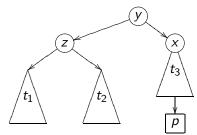

The complexity of Find is

# "Single" Rotation

▶ node z fails the AVL test after adding node p:

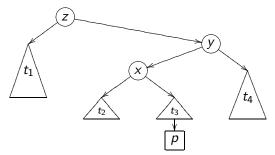

single rotation regains balance:

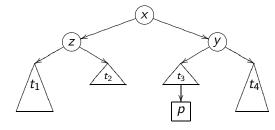

### "Double" Rotation

▶ Node z fails the AVL test after adding node p:

▶ Double rotation regains balance:

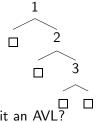

"Single" Rotation

▶ From an empty tree: Insert( 1 ), Insert( 2 )

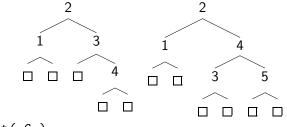

▶ Insert(3)

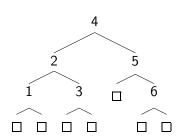

"Single" Rotation (Cont)

▶ Insert( 4 ), Insert( 5 )

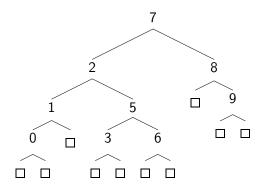

"Double" Rotation

▶ From an empty tree: Insert( 1 ), Insert( 3 )

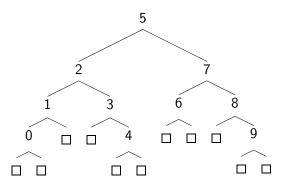

▶ Insert(2) 2 1 3

"Double" Rotation, Larger Example

▶ Insert( 4 )

"Double" Rotation, Solution of the large example.

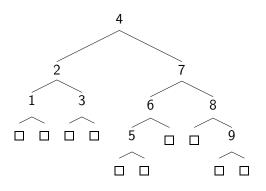

### Cost of Insert

- ▶ How many rotations may be required for an Insert? (A double rotation counts as one rotation.)
- ► How expensive is a rotation?
- ▶ Worst-case running time for Insert?

# **Examples of Deletion**

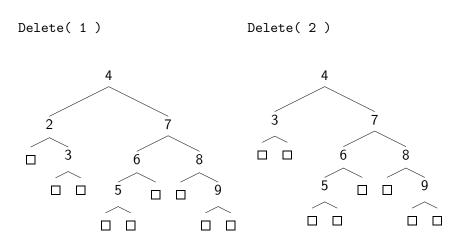

"Simple Rotation"

- ▶ Delete( 1 )
- ▶ Delete(2)

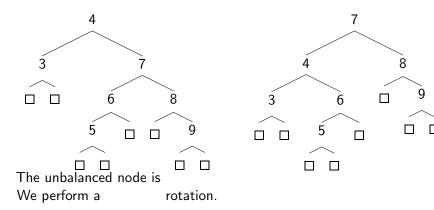

# **Examples of Deletion**

"Simple Rotation", solutions

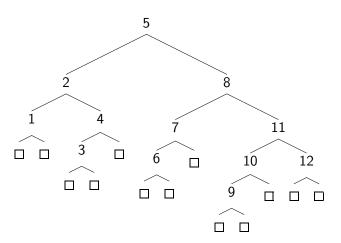

# **Examples of Deletion**

"Simple Rotation", solutions (cont)

### Delete

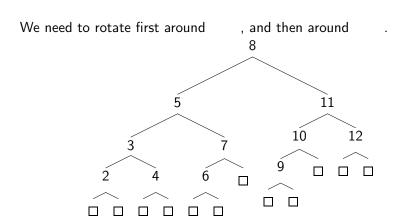

Larger Example

▶ Delete(1)

### Delete

Solution of large Example

### Cost of Delete

- ▶ How many rotations may be required for a Delete?
- How expensive is a rotation?
- ▶ Worst-case running time for Delete?

# Final Thoughts

- All major binary search tree operations have guaranteed worst-case Θ(log n) performance
- ► Fairly large constant hidden in order notation
- ► Each internal node stores a condition code (or height)
- ▶ Condition code is usually represented by  $\{-1,0,1\}$

# Summary

- AVL Trees are
- ► Their height is
- ▶ The time in which the operators are supported is
  - Search in
  - Insertion in
  - ▶ Deletion in
